Category:Autodesk Category:Computer-aided design softwareQ: Perl - Convert "big" floating-point numbers to integers I'm looking for a way to convert a list of floating point numbers to a list of integers. I don't care what the values are and no matter the order. For example, my @values = (2.4,1.9,-9.2); Should return [0,1,-8]; I'm looking for a perl solution, but since this is a one-off task, I could also run it in a shell script if that would be easier. A: You can use Math::BigFloat to convert strings into Bignums. use Math::BigFloat; my \$bignum = Math::BigFloat->new('2.4'); my @int_array = map { \$bignum->get_int(\$_) } split /\./, '-9.2'; Or, for an array of strings, use Math::BigFloat; my @float_array = map { \$bignum->get_str(\$_) } split /\.(d+)/, '2.4'; A: Here's a pure-Perl solution: use bigint; my @values = qw/ 2.4 1.9 -9.2 /; my @integers = map { bigint \$values[\$_] } 0..\$#values; Or, if you want the list of integers in the original order: my @integers = map { bigint \$values[\$_] } 0..\$#values; @integers = map { bigint \$values[\$_] } 0..\$#values; Note that if you're inputting a list of strings, you should not split them. Instead, you should split the string into parts separated by a d647c40b

The use of probes in controlled environments (e.g., a laboratory) for measurement of physical properties of a surface (e.g., resistivity or capacitance) is well known. While for most uses the measurement probe is immobile, in some applications it may be desirable for the probe to move about the measurement area, such as when the area to be measured is inaccessible for direct measurement (e.g., when the measurement area is in an airplane, ship, or other mobile platform). The use of a movable, handheld measurement probe for measuring surface properties in an inaccessible environment is described in U.S. Pat. No. 6,914,631 to Chou et al. (2002). Chou describes a method and apparatus for measuring the surface properties of a structure in a remote location, where the remote location is inaccessible to the remote probes and/or the structure. Chou uses an array of multiple probes to obtain the desired measurement. Each probe is made to move about the remote location, and an automated measurement system is used to detect when a probe has reached a desired position and to obtain a measurement from that probe. The use of multiple probes to measure the structure reduces the amount of time needed to obtain a measurement of the surface properties. The information obtained from the measurement may be transmitted to a central processing unit for use in the evaluation of the physical properties of the surface. The remote probe may be incorporated into an electrical connector for transmitting the measurement to the central processing unit. The central processing unit may be part of an apparatus to drive the remote probes as a whole or separate from any apparatus for controlling the remote probes, and may be used to control the remote probes without any knowledge of the measurement technique used to obtain the measurement.Q: Mac Catalyst Catalina App Store & software updates I am trying to find the answer to this in the Apple documentation but cannot find anything. On macOS Catalina (10.15.3), if I create a new Catalyst application in Xcode, what software updates and settings do I need to set in order for this to run on my Mac (AirPods Pro)? I am currently trying to find out if there is a way to remove the built-in Mac App Store, and there should be built-in software updates installed. A: Catalina requires that you have a Catalyst application installed and in Catalina Catalyst applications need to be listed on the Apple App Store. If you don't want to use the Apple App
